

In some situations, we may be only arranging part of a set of objects.

order matters <sup>6</sup>  
(Permutations)  
↓

**Example 5**

There are 15 students special events committee. They are organizing a party. They need one person to get drinks, one to get food, and one to find a location. In how many ways can these roles be assigned?

$$15 \times 14 \times 13 = 2730 \text{ ways}$$

Drinks                  Food                  Location

**Example 6**

How many four-digit passcodes can be created using the digits 1, 2, 3, 4, 5, 6? Repetition of the digits is not allowed.

$n=6$   
 $r=4$

~~$6 \times 5 \times 4 \times 3 = 360 \text{ ways}$~~

$6 \times 5 \times 4 \times 3 = 360$

$$\frac{n!}{(n-r)!}$$

$$\frac{6!}{(6-4)!} = 360 \text{ ways}$$

**Example 7**

How many four-digit passcodes can be created using the digits 1, 2, 3, 4, 5, 6? Repetition of the digits is allowed.

Repetition permitted  $\Rightarrow n^r \Rightarrow 6^4 =$   
per  $n$  different objects  
 $r =$  number of permutations

The number of permutations of "r" objects taken from a group of "n" objects can also be obtained by using the permutation formula:

$${}_n P_r = \frac{n!}{(n-r)!}$$

Most scientific calculators include a permutation function, which is usually labelled "nPr".
